

Week 2 Lecture - Research Sources

Undergraduate Research Methods in Psychology

Quinton Quagliano, M.S., C.S.P

Department of Psychology

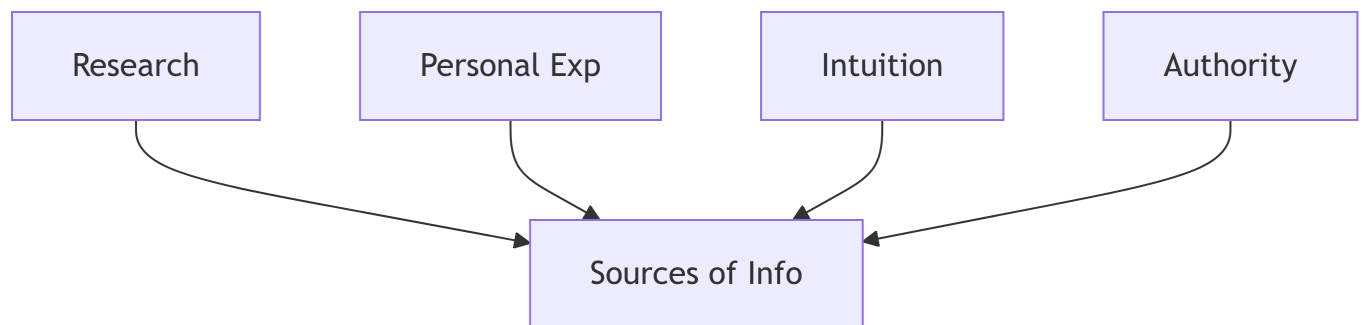

Table of Contents

1	Overview	2
1.1	Summary of Chapter	2
2	Research vs. Personal Experience	2
2.1	Overview	2
2.2	No Comparison	3
2.3	Experience is Confounding	4
2.4	Research > Experience	4
2.5	Probability in Research	5
3	Research vs. Intuition	6
3.1	Bias in Intuition	6
3.1.1	Convincing Narratives	6
3.1.2	Availability Heuristic	6
3.1.3	Present/Present Bias	7
3.1.4	Confirmation Bias	7
3.1.5	Bias Blind Spot	8
3.2	Intuitive Thinking vs Scientific (Empirical) Thinking	8
4	Research vs. Authority	8
4.1	Faults in Appealing to Authority	8
4.2	Flow Chart of Claims	9
5	Finding and Reading Research	9
5.1	Consulting Scientific Research	9
5.1.1	Types of Articles	9
5.1.2	(Edited) Books	10
5.2	Finding Research	10
5.3	Reading Research	10
5.3.1	The Usual Sections (Empirical Articles)	10
5.3.2	What are you Looking For?	11
5.4	Scientific Journalism vs Mis/Disinformation	11

1 Overview

1.1 Summary of Chapter

- We can gain _____ from many origins; this is true of both scientific and common sources and:
 - Scientific Sources:
 - * Journal _____
 - * Books and edited books _____
 - * Scientific _____
 - * etc. _____
 - Common sources:
 - * _____ outlets (and lots of them!)
 - * Newspapers
 - * Think tanks (private “research”)
 - * “Well my friend said...”
- *But*, how do we _____ these sources - which ones are the “best” for drawing conclusions? (hint: research!)
 - Also, how do we read each of these _____ more critically?
- We’ll compare 4 categories of sources:

2 Research vs. Personal Experience

2.1 Overview

- Personal experience is simply the _____ that comes at us from every-day life.
 - This is when we learn from the _____ that occur to and around us.
 - *Example:* I learn to walk carefully (like a penguin!) on ice because I have slipped in the past
-

- We often rely on personal experience to make _____, but this does not always mean it is the most reliable source of information...

2.2 No Comparison

- A **comparison group** is a key _____ between scientific research and personal experience. We must compare our study results to some other benchmark, whether that is a _____ group (no intervention) or another type of intervention.
- Without a comparison group we have three _____ outcomes:
 - Our effect is _____ than control (no intervention) or other interventions
 - Our effect is _____ to control or other interventions
 - Our effect is _____ than control or other interventions

- Example: A researcher performs a social intervention to reduce feeling of hostility towards an “out-group”. It seems like the participants don’t harbor any major negative feelings towards the out-group at the end of the study. A success!? Maybe...
 - **Discuss:** Why are the conclusions wrong here? What could we compare the social intervention group against?
- You may have some belief about the _____ of an intervention (from personal experience), but you won’t have good _____ of its “real” effect, without a comparison group.

2.3 Experience is Confounding

- Why did something happen? How can we know that A causes B? **Confounds** make it difficult to determine causation in our personal experiences. Confounds are variables that may change how or why something happens
 - You may sometimes hear of these confounds referred to as moderators and/or mediators
- Example: A professor addresses you in a disappointed tone on the first day of class. You assume it is due to them just disliking students.
 - **Discuss:** Why are the conclusions (potentially) wrong here? What other explanations are possible?
- Because of confounds, there may be these possibilities as well:
 - The professor had a rough day at home and it taking it out on students (unfairly)
 - You forgot your first assignment, and were late
 - The professor has mistaken you for a different student
 - Any number of other possibilities!
- In our own lives it is difficult to impossible to isolate individual causes for certain outcomes, but in research, we have procedural and statistical controls

2.4 Research > Experience

- In research settings, we can better control for the effects of confounds, and create comparison groups
 - Example: Bushman's study (catharsis theory)
-

- Another tale of why scientific process > experience

2.5 Probability in Research

- Individual differences are expected in theories! There are exceptions/edge cases to all hypotheses and, as we mentioned in the last lecture, we cannot account for all possible scenarios with a single study.
- Research is always **probabilistic** which means it try to capture the majority of experiences or the net average of all cases
 - Which may mean your experiences may contradict the weight of evidence in the research body - but that doesn't mean that your experience or the research consensus is "wrong"

- Connect to your previous statistics class: conclusions are based on p-values, which, in turn, are essentially a probability of a certain outcome.
- A single case does not fully invalidate a theory or hypothesis. Instead, it may represent a unique case that differs in some way than the others.

3 Research vs. Intuition

3.1 Bias in Intuition

- Recall that intuition is often like a “hunch” or a “gut feeling”. We may describe intuition as being “pre-scientific.”
- Unfortunately, our intuition may be swayed by certain sources of bias in how we think...

3.1.1 Convincing Narratives

- Have you ever met someone who could really sell a story? Maybe a friend who is really good at making stuff up or a salesperson.
- Freud certainly could! Many of his early theories drew on observations that *seemed* reasonable enough, and his psychoanalytic theory is prevalent to this day.
 - This is a sort of “just-makes-sense” thought process, where we think - “well, naturally, it works that way”
- **Discuss:** can you think of any good stories that turned out to be false?
- However, this intuition can be an incorrect assumption (see Scared Straight program) and may prevent us from fully exploring whether things are actually as we think they are

3.1.2 Availability Heuristic

- Anyone afraid of shark attacks in the ocean?
 - You may think that they happen often, but really, they are exceedingly rare. But because of popular media and news hype, the idea of shark attacks is much more readily **available** cognitively
 - A **heuristic** is just a cognitive shortcut, it allows us to skip the process of thinking to come to conclusion. However, in the scientific theory-data-hypothesis cycle, it threatens to obscure what is actually going on
-

- This heuristic often causes over- or under- estimations of certain situations occurring

3.1.3 Present/Present Bias

- The **present/present bias** may be best understood as an extension of failing to account for comparison groups (see [No Comparison](#))
 - If we don't see a possible outcome, do we fully account for it? Remember Harlow's monkeys' third option...
- This may be understood as also reflecting a tendency to recall certain (critical) events, but not others

	Expressed frustration (treatment present)	Did nothing (treatment absent)
Felt better (outcome present)	5 Present/present	10 Absent/present
Felt worse (outcome absent)	10 Present/absent	5 Absent/absent

3.1.4 Confirmation Bias

- This is our tendency to protect our already closely-held beliefs by selectively praising, criticizing, and noticing information that reinforces the belief
 - *Especially* relevant to situations like politics, where people have a great motivation to protect “their” perspectives
- This often causes extreme bias in evidence-gathering and is likely to lead to a single conclusion: “I’m right”
- Example:
 - Google search: “Evidence that the earth is flat” vs.
 - “Evidence of the earth’s shape”

3.1.5 Bias Blind Spot

- Recall those last few examples of bias? *You* are just as susceptible to those same fallacies as anyone else.
- It pays dividends to be humble and curious towards possibilities, even when our intuition, experiences, and even research may say otherwise.
- Especially as scientists, there is a temptation to believe *we* are uniquely resistant to bias, *we aren't*
 - Want to eliminate bias? Prove it with sound science, methods, and reporting

3.2 Intuitive Thinking vs Scientific (Empirical) Thinking

- Taken together, there are lots of ways that intuition and personal experience can let us down in the general conclusions we make
- In science, we are interested in using *empirical* principals to guide our thinking and writing, as to capture the overall trends in data and phenomena (remember, science is probabilistic)
- Simply “conducting research” does not inherently protect us from biases - we must be keenly mindful of the risks on biases in our research processes, starting with literature reviews

4 Research vs. Authority

4.1 Faults in Appealing to Authority

- We tend to trust many authorities throughout our lives: parents, teachers, professors, textbooks (via their authors), administrators, etc.
 - However, we ought to distinguish between trusting *a person* for their perceived expertise and trusting *a process* for producing sound claims
 - Why do we trust journal articles? It isn't just because the researchers are “published”, but rather, that the peer-review process is well set up to prevent poor science from slipping through
 - Therefore, we must interrogate *the method* by which a person comes to a conclusion, rather than basing our opinion of the person. This is the purpose of written articles, to interrogate the *how*, rather than the *who*
-

4.2 Flow Chart of Claims

Pg. 121 chart - Great reference to sort through how a certain conclusion may be reached

5 Finding and Reading Research

5.1 Consulting Scientific Research

5.1.1 Types of Articles

- **Original Empirical Journal Articles:** Some form of original study in which a scientific process and analysis were conducted. These are often some type of novel observation or experiment. Usually contains some form of introduction, methods, results, and discussion.

- **Literature Review Journal Articles:** A comprehensive literature review that summarizes, synthesizes, and compounds the many available empirical studies in a specific research area. Often, comes across as an extended introduction section.
 - Also, a great starting point when doing a literature review for your own study!
- **Meta-analysis:** An extension of a literature review articles that calculates a composite effect size from the surveyed research study. A more quantitative version of a classic literature review.

5.1.2 (Edited) Books

- **Scientific Books:** a full-length scientific book written by the same single or multiple authors throughout. Focuses on a single topic, and functions as a sort of extended literature review.
- **Edited Books:** a collaborative effort in which many experts compose chapters on specific topics. These are usually not peer-reviewed to the same extent as journal articles - but the authors are usually some of the most respected researchers in an area. Be careful of appeal to authority because of this!
 - These are popular among applied practitioners of psychology (consumers), because it allows them to keep up with developments and ideas in a nice range of areas.

5.2 Finding Research

We will cover this in a separate workshop/presentation! This is a critical skill to develop as an early researcher, and is fairly complicated.

5.3 Reading Research

5.3.1 The Usual Sections (Empirical Articles)

- **Abstract:** The publicly available summary of the entire paper
 - **Introduction:** The literature review and scaffolding towards the present research question
 - **Method(s):** Contains all relevant information about procedures and measures
 - **Results:** Often the results of statistical analyses
 - **Discussion:** Connecting the results to the practical implications of the findings and the existing literature review
-

- References: An alphabetical list of all the cited resources throughout the paper

5.3.2 What are you Looking For?

I like to work backwards:

- What conclusions does the author(s) make? What implications does this have and what limitations do they note (Abstract and Discussion)
- What is the current state of the literature, and what “gap” was the author trying to address? What was the core hypothesis of the study? (Introduction)
- Given the nature of the hypothesis, were the methods reasonable and ethical? Did they use ideal measures to capture the construct? What measurements were collected, and how was the planned analysis appropriate to this scenario? (Methods)
- Did they report relevant results to support the research? Were the statistics properly calculated and interpreted? (Results)
- Connect the results and discussion, were those final conclusions in line with what was reported in the results? (Between Discussion and Results)

In simple, do the conclusions have good, strong evidence to back them up? More extreme conclusions require more powerful evidence!

- Consider an article with the theory-data-hypothesis framework: what is the theory? What is the hypothesis? What is the data concluding?

5.4 Scientific Journalism vs Mis/Disinformation

- Empirical articles will *always* be the preferred way to gain scientific knowledge. Edited books, literature reviews, meta-analyses, et al. may all be good secondary sources as well.
 - However, popular scientific journalism may help you find new, relevant findings to your interests
 - See compare and contrast table between journal articles and journalism goals on pgs 136 - 137
-
